

# Dimensionality reduction

December 7, 2016

# Outline

## Principal Component Analysis

- ▶ What is it?
- ▶ Extensions
  - ▶ Sparse PCA
  - ▶ Simultaneous Component Analysis (SCA)
  - ▶ Independent Component Analysis (ICA)

# Unsupervised learning: Dimension reduction

- ▶ Goal: Estimate a probability distribution  $P(X)$
- ▶  $X$  mostly multivariate, possibly **huge**  $p$
- ▶ Different characteristics of interest
- ▶ Trying to find a density function  $\hat{P}(X)$  that is close to  $P(X)$

	X1	X2	X3	X4	X5	X6	X7	X8	X9	X10
1

3										
4										
5										
6										
7										
8										
9										
...										
n										

# PCA: What is it?

Goal: Reduce matrix  $X$  of dimension  $p$  to alternative matrix  $T$  of dimension  $r$

- ▶  $p$  = number of variables
- ▶  $r$  = number of components
- ▶ with  $r < p$

# PCA: What is it?

Dimension reduction by taking **orthogonal linear combinations** of the original variables such that the new dimensions contain as much variance as possible

$$T = XP$$

- ▶  $T$  = standardised component scores ( $n \times r$ )
- ▶  $X$  = original standardised data matrix ( $n \times p$ )
- ▶  $P$  = component loadings ( $p \times r$ )

# PCA: What is it?

Dimension reduction by taking linear combinations of the original variables

$$T = XP$$

1. Constrain variance to 1:  $\sum P^2 = 1$
2. Each linear combination is orthogonal with the others:  
 $T_j^T T_g = 0$
3. Each linear combination explains as much variance as possible:  
 $var(T_i) > var(T_{i+1})$

# PCA: What is it?

Dimension reduction by taking **orthogonal linear combinations** of the original variables such that the new dimensions contain as much variance as possible

$$T = XP$$

- ▶  $T$  = standardised component scores ( $n \times r$ )
- ▶  $X$  = original standardised data matrix ( $n \times p$ )
- ▶  $P$  = component loadings ( $p \times r$ )
  - ▶ combination of eigenvectors and eigenvalues

# PCA: What is it?

- ▶ Eigenvectors: direction of maximal variance
- ▶ Eigenvalues: scale of maximal variance

# PCA: What is it?

Singular value decomposition (SVD)

$$X = USV^T$$

- ▶  $X$  is the original  $n \times p$  data matrix,
- ▶ columns of  $n \times n$  matrix  $U$  contains the left-singular vectors,
- ▶ columns of  $p \times p$  matrix  $V$  contain the right-singular vectors,
- ▶  $S$  is a diagonal  $n \times p$  matrix that contains the singular values in descending order.

# PCA: What is it?

Singular value decomposition (SVD)

$$X = USV^T$$

$$T = XP$$

$$T = \sqrt{n-1}U \text{ (= standardised scores)}$$

$$P = \frac{SV^T}{\sqrt{n-1}} \text{ (= loadings)}$$

# PCA: What is it?

Singular value decomposition (SVD)

$$X = USV^T$$

$US$  = *principal scores*

$V^T$  = *principal directions (= eigenvectors)*

# PCA: What is it?

Least squares minimisation problem

$$(\hat{T}, \hat{P}) = \underset{T, P}{\operatorname{argmin}} \|X - TP^T\|_2^2$$

# PCA: What is it?

Based on some cut-off, take the first  $r$ -components

- ▶ Proportion variance explained: Choose all components until they cumulative explain certain amount of variance
- ▶ Eigenvalue criterion: Choose all components with eigenvalues higher than 1
- ▶ Scree plot: Look at the graph of the components and their eigenvalues. Choose all components before the 'elbow'

# PCA: What is it?

## PCA: What is it?

## Extensions: Sparse PCA

- ▶ Manually (e.g. set all loadings  $< 0.3$  to 0)
- ▶ Penalty, such as lasso

$$(\hat{T}, \hat{P}) = \underset{T, P}{\operatorname{argmin}} \|X - TP^T\|_2^2 + \lambda_l \|P\|_1$$

# Extension: Simultaneous Component Analysis (SCA)

Integrate over multiple data blocks  $K$  with either

- ▶ common subjects (T) or
- ▶ common variables (P)

# Extension: Simultaneous Component Analysis (SCA)

# Extension: Simultaneous Component Analysis (SCA)

## Extension: Simultaneous Component Analysis (SCA)

Integrate over multiple data blocks  $K$  with common subjects (T)

$$(\hat{T}, \hat{P}_k) = \underset{T, P_k}{\operatorname{argmin}} \|X_k - TP_k^T\|_2^2$$

## Extension: Sparse SCA

$$(\hat{T}, \hat{P}_k) = \underset{T, P_k}{\operatorname{argmin}} \|X_k - TP_k^T\|_2^2 + \sum (\lambda_g \sqrt{J_k} \|P_k\|_2 + \lambda_e \|P_k\|_{1,2})$$

- ▶  $\lambda_g$  group lasso penalty: Selecting groups
- ▶  $\lambda_e$  elitist lasso penalty: Selecting variables within groups

## Extension: Independent Component Analysis (ICA)

In PCA, you maximise a second-order moment (variance).

In ICA, you maximise higher order moment.

# Extension: Independent Component Analysis (ICA)

Standardised data  $X$  is a linear mixture of **independent, non-Gaussian** source signals

$$X = AS^T$$

- ▶  $X$  = Data
- ▶  $A$  = Mixing weights
- ▶  $S$  = Independent components ( = sources)

## Extension: Independent Component Analysis (ICA)

Maximise **independence** of components

- ▶ Minimise mutual information (maximum entropy)
- ▶ Maximise non-Gaussianity (kurtosis)

# Extension: Independent Component Analysis (ICA)

# Extension: Independent Component Analysis (ICA)

Use ICA when data are not

- ▶ Gaussian
- ▶ stationary
- ▶ linear

# Extension: Independent Component Analysis (ICA)

ICA **cannot**

- ▶ identify the number of source signals
- ▶ uniquely order the source signals
- ▶ properly scale source signals

Often PCA as preprocessing step

## Rotation: What is it about?

- ▶ Goal: Make PCA results more interpretable
- ▶ How: Rotate  $T$  and  $P$  as to make  $P$  as sparse as possible.

Rotated loadings do not respond to orthogonal eigenvectors
